

ALGAE HOPE

A new vision of renewable energy, always trying to find something new or re-think the existing environment to fit and put to better use. In this case it was thought in the micro algae as a renewable energy because fossil fuels are running out, but mostly because of the pollution that is around in all our environment.

Increasing talk over CO2 emissions and global warming, so this project is looking for ways to reduce these emissions, but mostly as grasp. Because the goal of Copenhagen is to reduce CO2 emissions 50% in 2025 to become a city free of emissions in 2050. And one of the ways to combine renewable energy and CO2 capture is by means of algae. Since CO2 is used (among others) to feed micro algae.
